1 Introduction

The ag++ program provides a more intuitive frontend to the AspectC++ weaver (ac++) in a GNU environment. The only preliminaries are a working installation of GNU C++ compiler, which also can run within a cygwin environment. It basically wraps the functionality of the aspect weaver and the c++ compiler into one single program.

2 Invocation

The usage of ag++ is mainly influenced by the usage of the GNU g++ compiler and the synopsis is like:

```
ag++ [options] [files...].
```

Let's say, you want to compile a single file (here: main.cc) with g++, you have to run

```
q++ -c main.cc
```

in order to generate an object file.

To weave and compile a single file you simply invoke

```
ag++ -c main.cc
```

the same way like you did before with g++.

2.1 Concept

As ag++ is just a wrapper, it first generates the puma configuration file, then calls ac++ and afterwards g++. The intermediate files generated by ac++ are stored in the directory which is extracted from the $-\circ$ option or in current directory. In some cases this may lead to a situation where the names of intermediate files interfere with each other.

2.2 Options

All available options are summed up in the options table (see table 1). The column labeled with AC++ shows if the option is taken over from ac++ by ag++ ('X'), not supported by ac++ ('-') or modified by ag++ ('!'). All options which are taken over, are not described in this document. Consult the AC++ Compiler Manual instead. Options which are not listed in the option table are accounted as g++ options. Some g++ options can not be automatically handled correctly by the options parser of ag++. So all g++ options starting with -p, -a, -d and -r (e.g. -pipe, -ansi, -dletters, -remap) have to be written between --Xcompiler (see 2.2.12) and --Xweaver (see 2.2.13). If such options passed to ag++ without using --Xcompiler they will be interpreted a ag++/ac++ options; e.g. -pipe will be interpreted as -p "ipe".

2 INVOCATION 2.2 Options

Option	AC++	Description	
gen_config	_	Only generate Puma configuration file	
weave_only	_	Weave only	
-c	!	Compile only	
keep_acc	_	Keep woven source code files	
c_compiler <arg></arg>	_	Path to C++ compiler	
ac_compiler <arg></arg>	_	Path to AspectC++ compiler	
config_command <arg></arg>	_	Specify command which prints information	
		about compiler	
Xcompiler	_	In case of doupt account following options as	
		g++ options.	
Xweaver	_	In case of doupt account following options as	
		ac++ options.	
-p path <arg></arg>	!	Defines a project directory	
-d dest <arg></arg>	Х	Specifies a target directory for saving	
-v verbose <arg></arg>	!	Level of verbosity (0-9)	
-o output <arg></arg>	Х	Name of the output file	
include_files	X	Generate manipulated header files (short ver-	
		sion -i is not supported)	
-a aspect_header <arg></arg>	!	Name of aspect header file or 0	
-r repository <arg></arg>	X	Name of the project repository	
config <arg></arg>	!	Parser configuration file	
no_line	X	Disable generation of #line directives	
-k keywords	X	Allow AspectC++ keywords in normal project	
		files	
real-instances	Х	Let ac++ perform a full template analysis	
problem	Х	Enable back-end compiler problem workaround	
no_problem	Х	Disable back-end compiler problem workaround	
warn	Х	Show a specific ac++ warning that is sup-	
		pressed by default	
no_warn	Х	Suppress a specific ac++ warning	
-I <arg></arg>	Х	Include file search path	
-D <name>[=<value>]</value></name>	Х	Macro definitions	
-U <name></name>	Х	Undefine a macro	
include <arg></arg>	Х	Forced include	

Table 1: ag++ Compiler Option Summary

2.2 Options 2 INVOCATION

2.2.1 --gen_config

Just create a parser configuration and quit afterwards. The argument of the -o option specifies the name of the file. In any other case (no --gen_config and/or no -o option) a configuration file with the name 'puma.config' will be generated in the directory where ag++ was invoked.

2.2.2 --weave_only

Generate only woven source code files. With $-\circ$ option and one file the generated output is named after the argument of the $-\circ$ option.

2.2.3 --path

This options differs only slightly from the --path option of ac++. In ac++ it is mandatory to specify a project path, whereby ag++ the current working directory is used as project path by default. Especially for larger projects it is NOT wise to rely on the default project path, as weaving take a lot of time. See the AspectC++ Compiler Manual for a more detailed description of this option.

2.2.4 - c

Like the -c option of g++, this options effects the creation of object files of one or more source files.

2.2.5 -v|--verbose [<arg>]

Set the level of verbosity.

2.2.6 --aspect-header <arg>

This option differs from meaning in ac++ only if dependencies are generated (see 2.3).

2.2.7 --keep_acc

Don't remove intermediate .acc files generated by ac++.

2.2.8 --c_compiler

Specify path to GNU C++ compiler The default is g++.

2.2.9 --ac_compiler

Specify path to AspectC++ compiler By default ag++ assumes, that the ac++ executable is located in the same directory like itself.

2.2.10 --config_command

Specify the command which prints information about the compiler. This information is necessary for generating the parser (puma) configuration file. The default value is "<compiler> <compiler> compiler options> -E -dM -v -x c++ <an empty file>".

2.2.11 --config <arg>

Path to a puma configuration file. If this option is available the configuration file will not be generated automatically.

2.2.12 --Xcompiler

ac++ and ag++ options that might interfere with g++ options are not recognized after using --Xcompiler in the argument list of an ag++ invocation.

2.2.13 --Xweaver

Enable the recognition of those ac++ and ag++ options which previously have been disabled by the usage of -Xcompiler.

2.3 Generating dependency information

To produce dependency files just pass the $-\mathbb{M}$ or $-\mathbb{M}\mathbb{M}$ (consult the GNU C++ Compiler Manual) to ag++. Dependency files generated by ag++ are slighty different from dependency files created by g++, as they contain dependencies to aspect header files. If the --aspect-header option is provided, only the header file specified as option argument is considered when building the dependency file; otherwise the dependency file will contain all aspect header files within the whole project path .

2.4 Examples

ag++ --help
 Displays all options with a short description.

2.4 Examples 2 INVOCATION

ag++ -o test Test.cc main.cc
 Weave, compile and link the source files Test.cc and main.cc. The created executable will be named 'test'.

• ag++ --gen_config

Create a puma configuration file named puma.config within the current working directory.

- ag++ --gen_config -o my.config
 Create a puma configuration file named my.config.
- ag++ --path src --include_files --dest gen/includes

 Generate modified include files out of all include files found below src directory and store them under 'gen/includes'.
- ag++ -M -MFmain.dep main.cc

 Generate dependency file main.dep from source file main.cc.
- ag++ -p ../aspects -p . --Xcompiler

 This string could be used to substitute g++ in a simple make environment.
